CONCLUSIONS

Molecular dynamics studies elucidate the nature of the boundary conditions and the slip length at solid-fluid interfaces.

Maxwell's scenarios of behavior near the wall realized only in the limiting cases - crossover complicated

The slip length (also in thermal slip) is a sensitive function of the wall-fluid interactions and of the density

Reconstruction in the density profile near the wall leads to a maximum in the flow velocity as a function of density

Mixed wettability channels generate stationary plug flows in the non-wetting regions. Different crossovers from wetting to non-wetting regions for the dense and Knudsen cases.

Hydrophobic patterned surfaces give rise to the lotus-like behavior

21 μm \times 100 μm

Predictor-corrector schemes Rahman, Phys. Rev. A 136, 405 (1964)

Fifth-order predictor-corrector method due to C. W. Gear

*Numerical Initial Value Problems in Ordinary
Differential Equations, Prentice-Hall, 1971*

PREDICTOR-CORRECTOR

Prediction: molecular positions r_i and their first five time-derivatives at time $(t+\Delta t)$ are predicted by Taylor's expansion from their values at time t

Evaluation: force on each molecule F_i at time $(t+\Delta t)$ is calculated using the predicted positions

Correction: an error term in the acceleration Δa_i is obtained from the difference between the predicted acceleration and that given by the force F_i . This error is used to correct the predicted positions and their time-derivatives

Characteristic time $\tau = \sigma \sqrt{m/\epsilon}$

ARGON: $\tau = 10$ fs

Divide into small time intervals $\Delta t = \tau/200$

A box with the periodic boundary conditions - if possible

$X = x_i$ $X^m = x^{(m)}_i (\Delta t)^m / m!$ The m'th derivative $m=0,1,2,3,4,5$

$$X^P(t+\Delta t) = X(t) + X1(t) + X2(t) + X3(t) + X4(t) + X5(t)$$

$$X1^P(t+\Delta t) = X1(t) + 2X2(t) + 3X3(t) + 4X4(t) + 5X5(t)$$

$$X2^P(t+\Delta t) = X2(t) + 3X3(t) + 6X4(t) + 10X5(t)$$

$$X3^P(t+\Delta t) = X3(t) + 4X4(t) + 10X5(t)$$

$$X4^P(t+\Delta t) = X4(t) + 5X5(t)$$

$$X5^P(t+\Delta t) = X5(t)$$

Error: $\Delta X2 = X2(t+\Delta t) - X2(t)$

α_m depend on the degree of the differential equations and on the order of the Taylor series used: to ensure numerical stability

$$X(t+\Delta t) = X^P(t+\Delta t) + \alpha_0 \Delta X2$$

$$X1(t+\Delta t) = X1^P(t+\Delta t) + \alpha_1 \Delta X2$$

$$X2(t+\Delta t) = X2^P(t+\Delta t) + \alpha_2 \Delta X2$$

$$X3(t+\Delta t) = X3^P(t+\Delta t) + \alpha_3 \Delta X2$$

$$X4(t+\Delta t) = X4^P(t+\Delta t) + \alpha_4 \Delta X2$$

$$X5(t+\Delta t) = X5^P(t+\Delta t) + \alpha_5 \Delta X2$$

5'th order:

$3/16, 251/360, 1, 11/18, 1/6, 1/60$

3'rd order:

$1/6, 5/6, 1, 1/3$

Calculation of the forces: the most time-consuming part of an MD simulation

$N(N-1)/2$ pairs of atoms

Cutoff r_c : $r_{ij} > r_c$ then $F=0$

$r_c = 2.5\sigma$ or 2.2σ

Verlet list: for each particle keep a list of neighboring atoms that lie within a distance r_L of i , where $r_L > r_c$ (slightly)

Update the list periodically, say, every 10 steps.

$r_L = r_c + 0.3\sigma$ - typically 40 neighbors

Study diffusion of one atom to
distinguish between liquid and solid

Temperature, energy, correlations,
pressure from the virial theorem

Velocity profiles change little along the channel

Density profiles do change: coating of the walls

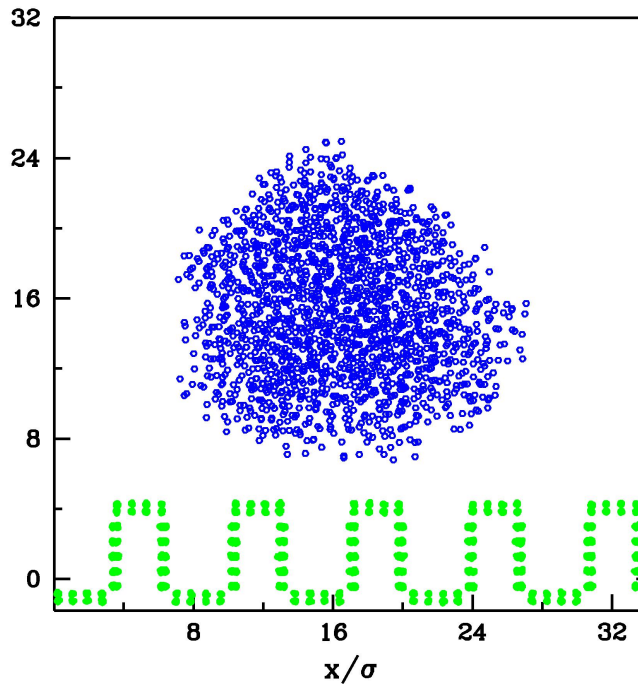

A non-wetting fluid droplet moving along a nanocomb

A horizontal
pressure gradient

Acceleration of the center of mass goes
down on making the 'canyons' deeper

$A=3/16$
 $T=0.8$

movement
